The quantization of gravity is widely believed to result in gravitons – particles of discrete energy that form gravitational waves. But their detection has so far been considered impossible. Here we show that signatures of single graviton exchange can be observed in laboratory experiments. We show that stimulated and spontaneous single-graviton processes can become relevant for massive quantum acoustic resonators and that stimulated absorption can be resolved through continuous sensing of quantum jumps. We analyze the feasibility of observing the exchange of single energy quanta between matter and gravitational waves. Our results show that single graviton signatures are within reach of experiments. In analogy to the discovery of the photo-electric effect for photons, such signatures can provide the first experimental clue of the quantization of gravity.

This research has made use of data or software obtained from the Gravitational Wave Open Science Center (gwosc.org), a service of the LIGO Scientific Collaboration, the Virgo Collaboration, and KAGRA. This material is based upon work supported by the National Science Foundation under Grant No. 2239498, the European Research Council under grant no. 742104, the Swedish Research Council under grant no. 2019-05615, the U.S. Department of Energy, Office of Science, ASCR under Award Number DE-SC0023291, the Branco Weiss Fellowship – Society in Science, the General Sir John Monash Foundation, and the Wallenberg Initiative on Networks and Quantum Information (WINQ).
